FOREWORD

This report was prepared by the National Bureau of Standards, Washington, D. C., under USAF Purchase Order (33-038)51-4063-E. The contract was initiated under the research and development project identified by Expenditure Order No. 540-20, and it was administered under the direction of the Power Plant Laboratory, Engineering Division, Air Materiel Command with Mr. I. F. Littman and Mr. H. C. Rodean acting as project engineers.

USAF-TR-6455

ABSTRACT

This report presents the results of performance tests on a group of twelve Chromel-Alumel thermocouples currently being used in jet engine testing and operation. The tests include the determination of rate of response and recovery factor, and the calibration of the thermocouples for the effects of radiation and conduction losses. The results are presented in the form of tables and charts to facilitate a direct comparison of the performance characteristics of the test units.

PUBLICATION REVIEW

The publication of this report does not constitute approval by the Air Force of the findings or the conclusions contained therein. It is published primarily for the exchange and stimulation of ideas.

INTRODUCTION

In accordance with a request from AMC (Ltr. MOREXP13/IFL/mad, 7 Sept. 1950) and in cooperation with engine manufacturers of the Aircraft Industries Association, a program of tests was undertaken to determine the performance characteristics of a group of Chromel-Alumel thermocouples currently being used in jet engine testing and operation. The thermocouples included in the tests were selected by the engine manufacturers on the basis of service requirements and previous test experience. The following performance characteristics were determined: (1) rate of response, (2) recovery factor, and (3) wall temperature effects.

DESCRIPTION OF TEST THERMOCOUPLES

A total of 12 different thermocouple units from five engine manufacturers was submitted for the tests. In most cases, only a brief general description of the unit was supplied.

A. Thermocouples submitted by Allison Division, General Motors Division.

1. Allison Part No. 6714720; abbreviated designation Al-1; shown photographically in figure 1. This is a sampling-type thermocouple with screw-type terminals. The sheath is $1/4"$ in diameter and has three $0.09"$ diameter holes on the upstream side and one $0.12"$ diameter hole on the downstream side. The thermocouple junction is located at the discharge port.
2. Allison Part No. EX15334; abbreviated designation Al-2; shown photographically in figure 2A. This is an exposed tip thermocouple, commonly called the pencil-type. The tip extends about $1/4"$ beyond the support tube.
3. Allison Part No. 6710169, Revision J; abbreviated designation Al-3; shown photographically in figure 2B. This is an exposed twisted-type junction of about No. 16 gage wire. The junction extends about $1/4"$ beyond the porcelain insulator and the steel sheath.

B. Thermocouples submitted by The B. G. Corporation.

1. B. G. Model A-8412X2; abbreviated designation BG-1; shown photographically in figure 3A. This is a totally-enclosed Chromel-Alumel junction, of $0.010"$ wires packed in aluminum oxide powder within a tapered Inconel sheath. The thermocouple junction is about $1/16"$ from the tip of the sheath.

2. B. G. Model M-834 Modified; abbreviated designation BG-2; shown photographically in figure 3B. This is an exposed junction of No. 18 gage wires. The junction protrudes about $3/16$ " beyond the insulator and the metal support tube.
3. B. G. Model M-834 Standard; abbreviated designation BG-3; shown photographically in figure 3C. This is a No. 18 gage thermocouple located within a total-temperature well.

C. Thermocouple submitted by General Electric Company

1. G. E. No. 8947403 Gr. 2 thermocouple; abbreviated designated GE-1; shown photographically in figure 4. This is a loop-type thermocouple with a butt-welded junction. The wires are about No. 18 gage and have been dressed down to be approximately rectangular in cross section.

D. Thermocouples submitted by Pratt and Whitney Aircraft

1. Manning, Maxwell and Moore Type 155A; abbreviated designation PW-1; shown photographically in figure 5A. This is a pencil-type thermocouple supported in a metal tube. Two small discs are located near the tip of the thermocouple.
2. Pratt and Whitney Part No. 153286A; abbreviated designation PW-2; shown photographically in figure 5B. This is a total-temperature type thermocouple probe with a bare junction located within the stagnation zone.
3. Pratt and Whitney Part No. 1b1473; abbreviated designation PW-3; shown photographically in figure 6A. This is a thermocouple which is totally enclosed in a rather short heavy tube. The thermocouple is grounded to the well, with the junction apparently welded to the end of the tube.
4. Pratt and Whitney Part No. 131149; abbreviated designation PW-4; shown photographically in figure 6B. This is a special design of thermocouple probe employing several coaxial tubes apparently as radiation screens. The thermocouple is welded to the innermost screen. The outer tube of the probe is $3/4$ " in diameter and 5" long. Because of the size and design of this unit it was not practicable to obtain a satisfactory radiation-conduction calibration of the thermocouple in the test facilities on hand.

E. Thermocouple submitted by Westinghouse

1. Westinghouse Jet Engine Thermocouple; abbreviated designation W-1; shown photographically in figure 7. This is an

exposed twisted-junction type of thermocouple of about No. 18 gage wire. The junction protrudes about $1/4$ " beyond the end of the porcelain insulator and metal support tube.

RESPONSE RATE TESTS

The rate at which a temperature-sensing element located in the gas stream of a jet engine responds to sudden changes in gas temperature is of great practical importance in the control and operation of such an engine. An acceptable control system must prevent the engine speed from increasing at an excessive rate and protect critically stressed parts from being overheated. Since a change in fuel-air ratio is normally accompanied by a simultaneous change in gas temperature, adequate protection of the power plant requires a control that will act very suddenly to limit the rate of change of gas temperature whenever it exceeds a safe value. If the control is temperature actuated, the sensing element must therefore respond rapidly when subjected to a change in temperature.

When the temperature of a gas stream in which a thermocouple is immersed is increased instantaneously, the increase, ΔT , in the temperature of the junction with time, t , thereafter is given by the equation:

$$\Delta T = (T_2 - T_1)(1 - e^{-t/\tau}) \quad (1)$$

where T_1 = initial temperature of the junction

T_2 = final steady temperature of the junction

e = 2.7183, the base of the Napierian system of logarithms

τ = a constant

From equation (1) we may write:

$$\Delta T / (T_2 - T_1) = 1 - e^{-t/\tau} \quad (2)$$

It is apparent from equations (1) and (2) that the quantity τ has the dimensions of time, and that at time $t = \tau$, equation (2) becomes:

$$\Delta T / (T_2 - T_1) = 1 - 1/e = 0.632 \quad (3)$$

This, τ , is the time required for the thermocouple junction to undergo 63.2 percent of the total change in temperature to which it is subjected instantaneously. The time τ , so defined is generally referred to as the "characteristic time" of the junction. Actually it is not a characteristic of the junction alone, but of

the junction and the system in which it is immersed, so that the gas flow rate must be specified simultaneously with the characteristic time.

The apparatus used for subjecting a thermocouple junction to a sudden change in gas temperature is shown in figure 8. It consists essentially of an Inconel tube which can be held in place around the thermocouple junction by a release plate, but which, upon removal of this plate, is pulled away by a spring. Thus the junction is suddenly exposed to the hot gas stream flowing through the test section. While the Inconel tube is in position around the test junction, cooling air is forced through the tube to keep the junction temperature at a selected low value.

The metering and recording system employed is shown schematically in figure 9. The thermal emf of the junction is converted into a pulsating direct current voltage by means of a vibrating reed-type chopper. This pulsating DC voltage is amplified and fed into a direct inkling Brush magnetic oscilloscope. The pen of the latter instrument vibrates with a frequency of 60 cycles per second and with an amplitude which is proportional to the thermocouple emf. The envelope of the oscilloscope record is thus a time record of the thermocouple emf, although not on an absolute scale. However, for the present purpose the scale is of no consequence, since it is desired only to measure the time required for the junction to undergo 63% of its total change in temperature. The time scale of each record can be established in either of two ways. For the junctions having rapid response, the 60 cycle oscillations can be counted. For the heavier junctions it is unnecessary to count the oscillations since the record paper is moved at known speeds by a synchronous motor through gears.

The response rate of each of the test thermocouples was determined at gas flow rates of 2, 4, and 6 lb/sec ft². In each instance the junction was subjected to a change in temperature from about 400°F to about 1000°F. A typical oscilloscope record is shown in figure 10A, and a large-scale plot of the time-temperature relation is shown in figure 10B.

A summary of the observed values of the characteristic times is given in Table I.

RECOVERY FACTOR TESTS

When an immersion-type instrument, such as a thermocouple, is used to measure the temperature of a gas moving at a velocity of about 300 ft/sec or higher, the thermal effect of the impact of the gas molecules against the sensing element becomes signifi-

cant if an accurate measurement of the gas temperature is to be made. Since the magnitude of the impact effect increases as the square of the gas velocity, errors of considerable magnitude may result at high velocities unless the impact effects are taken into account.

The effectiveness of a particular thermocouple for indicating the total temperature of a high-velocity gas stream is expressed by its recovery factor, r , defined as:

$$r = (T_i - T_s) / (T_t - T_s)$$

where T_i = temperature indicated by the thermocouple junction
 T_s = static temperature of the gas
 T_t = total temperature of the gas

The recovery factor tests were carried out in the apparatus shown diagrammatically in figure 11. Air is supplied by a Roots-Goodersville centrifugal blower having a capacity of 5000 cu ft of free air per min at a pressure of 5 lbs/in² gage. The flow rate is controlled by a valve at the blower outlet. The air flows through a straight 12-foot length of 12-in. pipe before discharging through a 4-in. nozzle to the atmosphere. A cup-type total-temperature thermocouple is mounted in the 12-in. pipe, one foot upstream from the nozzle entrance. A total pressure tube is also located in the pipe one foot upstream from the nozzle.

The junction of the thermocouple under test is supported in the air stream at the nozzle discharge. The terminal end of the couple is mounted in an aluminum block provided with an electric heating coil. A control thermocouple is located within the aluminum block. During a test, the power supplied to the heating coil was adjusted until the temperature of the block, and hence also that of the terminal end of the test thermocouple, was identical with that indicated by the junction of the test couple. Under this condition, heat losses from the junction by conduction along the thermocouple support tube are eliminated.

From the energy considerations applicable to a reversible adiabatic process, such as the flow of air through the nozzle used in the present system, it can be shown that the following relations hold at the nozzle discharge:

$$T_s = T_t (p_t / p_s)^{(v-1)/v} \quad (5)$$

$$T_t - T_s = V^2 / 2gJc_p \quad (6)$$

$$V = F/c \quad (7)$$

$$c^2 = VgRT_s \quad (8)$$

where T = temperature in degrees Rankine
 P = absolute pressure
 C_p = heat capacity at constant pressure = 0.24 Btu/lb °F
 γ = ratio of specific heats = 1.4 for air under present test conditions
 g = acceleration of gravity = 32.2 ft/sec²
 J = mechanical equivalent of heat = 778 ft lb/Btu
 V = velocity in ft/sec
 M = Mach number
 c = velocity of sound
 R = gas constant = 53.3 Btu/ft³ °F

The subscripts s and t refer to static and total conditions.

Since the total temperature and total pressure remain constant in the adiabatic expansion and compression of a perfect gas, the values of T_t and p_t observed upstream from the nozzle are applicable at the nozzle discharge. Since the nozzle discharges to the atmosphere, the static pressure (p_s) at the test thermocouple is the prevailing barometric pressure.

Thus from the observed values of T_t , $T_t - T_i$, p_t and p_s , the value of T_s at the test thermocouple, and hence also its recovery factor can be calculated from the above equations. A typical set of test data is shown in figure 12. The experimental values of $T_t - T_i$ are plotted against the velocity of the discharge from the nozzle in figure 12A. Calculated values of recovery factor are plotted against Mach number in figure 12B.

All test thermocouples exhibited recovery factors essentially independent of Mach number up to values of about $M = 0.7$. At higher values of M , the formation of local shock waves results in an unstable condition with a tendency toward higher recovery factors.

Table II summarizes the recovery factor test data. In each case the average value of recovery factor up to $M = 0.7$ is given.

CALIBRATION TESTS

The temperature attained by a thermocouple junction immersed in a stream of hot gas is seldom identical with the temperature of the gas itself, but instead is characteristic of a steady state at which the rate of heat transfer from the gas to the junction by convection is equal to the rate of heat transfer from the junction to the surroundings by radiation and conduction. In gas turbine and jet engine applications the effect of radiation losses on the indicated temperature is usually the more important, particularly at gas temperatures above 1200°F. However, conduction

effects become important when depth of immersion into the gas stream is limited and when heavy walled sheaths or supporting tubes are employed. For accurate temperature measurements, it is necessary to evaluate the radiation and conduction correction over the range of gas temperatures, gas flow rates and wall temperatures prevailing in service.

The calibration of each of the test thermocouples for the combined effects of thermal radiation and conduction was made by comparing the indications of test instrument with the indications of two silver-shielded Chromel-Alumel thermocouples which had previously been calibrated against a radiation- and conduction-compensated laboratory standard. Figure 13 is a photograph showing a test thermocouple and two silver-shielded thermocouples mounted in the cover plate of the test section. The wall temperatures were measured by means of four Chromel-Alumel junctions peened into the pipe wall, and gas flows were measured by means of a pitot tube in the gas stream and a static pressure tap in the pipe wall. Figure 14 shows the arrangement of the test equipment in the working section.

Calibration tests on each thermocouple* were made with gas temperatures ranging from 1000°F to 1500°F, wall temperatures from 500°F to 1200°F, and with gas flows of 2, 4, 6, and 8 lbs./ft.-sec. The calibration data are summarized in Tables III, IV, V, and VI. In evaluating the corrections for radiation and conduction losses, the emf-temperature relation of the wire in the thermocouples was assumed to correspond to the standard Chromel-Alumel reference table. It is believed that the corrections for radiation and conduction losses given in Tables III, IV, V, and VI are accurate to $\pm 5^{\circ}\text{F}$ when the corrections are less than 20°F and to one fourth of the correction when the latter exceeds 20°F .

CLOSURE

The purpose of the test program has been to obtain comparative performance data on commercial thermocouples designed for use in jet engines. This report has therefore been limited to the presentation of the observed experimental data with no discussion as to the relative merits of individual units. The results are presented in tabular form to facilitate a direct comparison of the performance characteristics of the test thermocouples.

*Because of the design and construction of thermocouple FW-4, it was not possible to obtain a satisfactory calibration of this unit.
